Mejora Genética Animal  
Madrid

A photograph showing a pig in a metal feeding trough. The pig is on the left, looking towards the trough. The trough is filled with a large pile of dark, textured feed. A metal shovel is stuck into the feed on the right. A vertical pipe or chute is in the center, with a smaller pile of lighter-colored feed at its base. The scene is dimly lit, with a strong light source from the right creating highlights on the trough's edge and the feed.

We need feed  
efficient animals

Energy from **food** = Energy in **product** + **Loss**

Output traits are selected *upwards* to *more* (no limit)

Input traits are selected *downwards* to *less* (limit = 0)

First law of thermodynamics: law of **conservation of energy**

= energy can not be created or destroyed, it can only be changed from one form to another

# Pig Breeding = selection for improved lean growth efficiency

- Increased growth rate
- Reduced body fatness
- Improved feed efficiency

But: improved leanness and feed efficiency  
= negatively correlated with feed intake

→ Selection resulted in decreased feed intake capacity

= Lower voluntary feed intake or appetite

→ Recommended to increase ad lib feed intake during entire growth period

Sows in commercial production systems originate from lean types of pigs:

During lactation sows must:

- Maintain a genetically increased litter size, a
- Genetically increased growth rate
- On reduced amounts of body fat reserves
- With a reduced appetite

→ Excessive mobilization of body reserves

= Frequent reproduction problems

→ Voluntary feed intake should be considered in breeding programs

This study:

To investigate the phenotypic correlation between growth, mature & lactation feed intake in a mouse model

# Material and Methods

104<sup>th</sup> Generation of selection experiment for litter size at birth

48 S-line: selected = 21 pups/litter

42 C-line: control = 10 pups/litter

## Feed intake measurements:

Growth: 21 to 42 d of age

Maturity: 42 to 69 d of age

Lactation: 1 to 21 d in lactation

Growth intake = Average intake 21 to 42 d

Mature intake = Linear between 42 and 69

Lactation intake = Linear between 5 and 14 d

Fits are 96 to 100% (average = 100%)

## Other parameters:

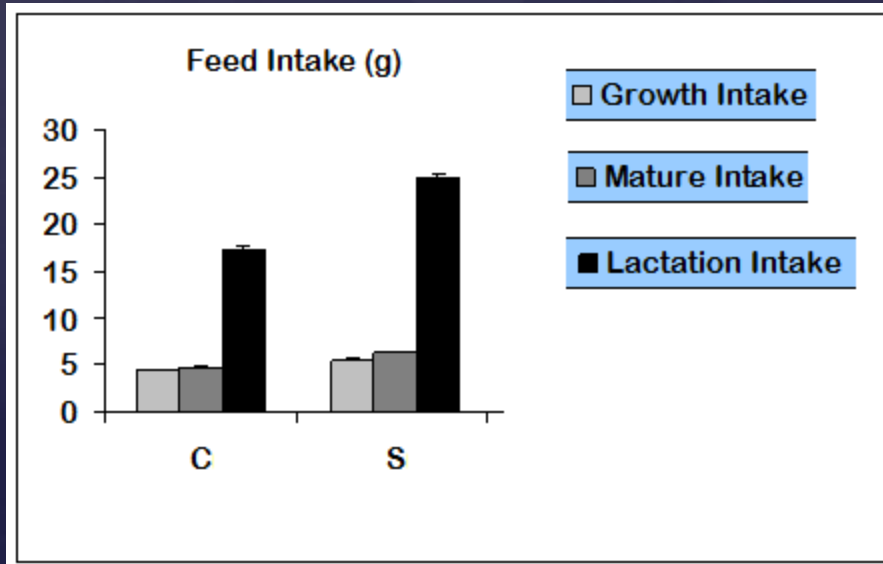

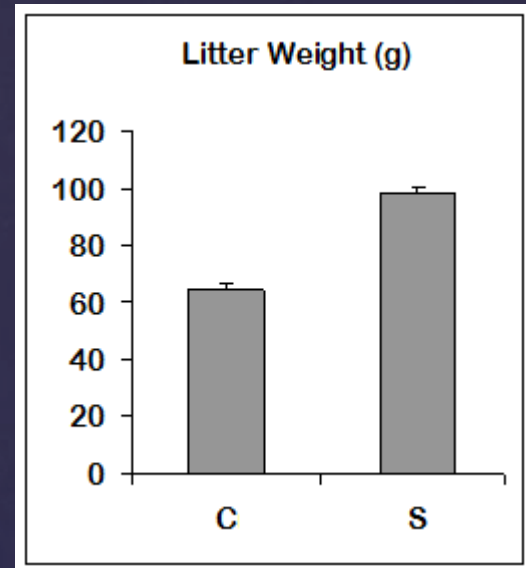

1. Litter size
2. Litter weight
3. Mature body weight (A)

$$Y_{ijk} = \mu + \text{Line}_i + \text{Stand}_j + e_{ijk}$$

(Interaction not significant)

# Results & Conclusions

## Growth & Mature intake:

	C	S
<b>Growth intake</b>		
Mature intake	0.63 <sup>***</sup>	0.67 <sup>***</sup>
Mature bodyweight	0.54 <sup>***</sup>	0.31 <sup>*</sup>
<b>Mature intake</b>		
Mature bodyweight	0.43 <sup>**</sup>	0.46 <sup>**</sup>

Growth and maturity = large influence of body size  
(maintenance requirement)

## Lactation intake:

Not influenced by size → Intake regulated by a different factor

	C	S
<b>Lactation intake</b>		
Mature bodyweight	-0.06	0.15
Litter size	0.77***	0.36*
Litter weight	0.94***	0.79***

# Growth & Mature intake vs. Lactation intake?

Correlation between lactation intake and growth & mature intake in S, but no correlation in C-line

When can we expect a positive correlation:

→ When they eat to their capacity (or a similar proportion thereof) in each period

**Control line:** lactation intake related to litter weight, not growth/mature intake

→ Animals with highest growth/mature intakes not necessarily have largest litters

**Selection line:** lactation intake related to litter weight and growth/mature intake

→ They eat to their potential (not as much as they should, but as much as they could)

Animals with highest growth/mature intakes also supported the largest litters (weight)

Results suggest that lactating Control females eat to support a given litter size

Lactating Selected females support the maximum litter weight that is allowed for by their intake capacity

Selected females have been 'genetically programmed' to eat to their potential intake capacity as a correlated effect, allowing for maximum lactation

Sows can be suggested to produce at their maximum potential

But: milk production is reasonably independent of energy intake → sows lose body weight

Possible: relationship not between growth and lactation intake, but between growth and body condition instead

Thanks
