# Dissected fat deposits for evaluation of total body fat percent in mink (*Neovision vison*)

Vivi Hunnicke Nielsen, D. Mayntz, A. Sørensen,  
S.K. Jensen, B.M. Damgaard and S.H. Møller

# Assessment of body fat content

- Whole body chemical analysis
- Body Condition Score (BCS)

---

# Study of dissected fat deposits as predictors of total body fat content in mink

- **Perirenal fat**
- **Subcutaneous fat in the groin region**

# Experimental setup

## 3 experimental lines (100 Females; 20 Males) (Brown mink)

- **AL-line: Selection for November weight on *ad libitum* feeding**
- **RF-line: Selection for November weight on restricted feeding**
- **FF-line: Farm fed control line with no selection**

**4-5 males and 5-6 females from each lines examined**

# Experimental setup

## Registrations at pelting:

- **Weight at pelting**
- **Body length**
- **Subcutaneous fat in the groin region**
- **Perirenal fat of both kidneys**
- **Total fat = Perirenal fat + Subcutaneous groin fat**

# Experimental setup

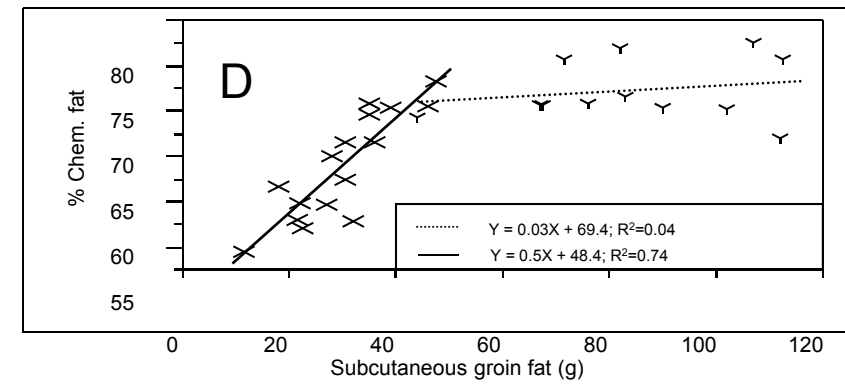

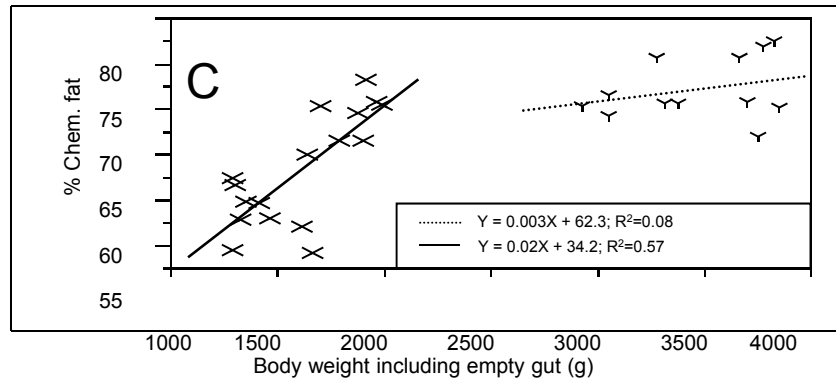

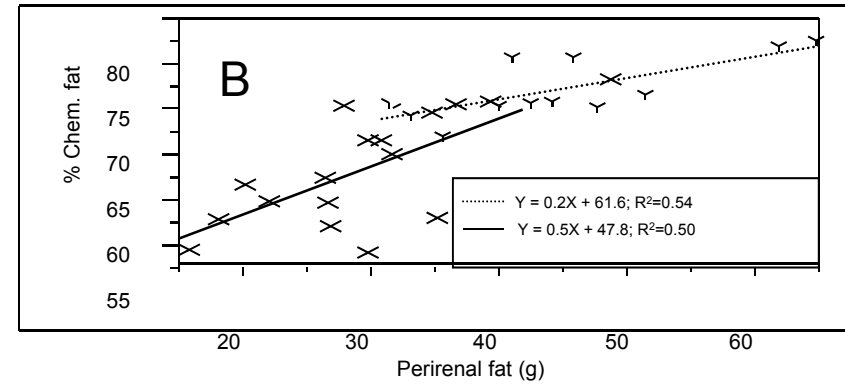

## Chemical analysis of whole bodies

- **Carcasses**
  - Autoclaved twice 120 min
  - Blended for 5 min
  - Freeze dried
- **Fat**
  - Soxhlet extraction

## Percent chemical fat (*P*-values)

Source of variance	Covariate				
	Body length	Body weight	Perirenal fat (1)	Subcutaneous groin fat (2)	Total fat (1+2)
Sex	0.53	0.14	0.10	0.07	0.12
Selection line	0.81	0.75	0.93	0.65	0.55
Covariate	0.07	0.0008	0.0002	<0.0001	<0.0001
Sex*covariate	0.02	0.01	0.09	<0.0001	0.0003

# Conclusions

## New procedure for estimating fat content in mink

- **Destructive**
- **Easy – many animals can be examined at pelting**
- **Objective measures of fat deposits**
- **Sum of perirenal fat and subcutaneous fat in the grin region is the best predictor of total body fat – in females ( $R^2 = 0.78$ )**
