

# The economic and environmental performance of grazing and zero-grazing systems for Dutch dairy farms

**Cindy W. Klootwijk**, C.E. Van Middelaar, A. Van den Pol-van Dasselaar, P.B.M. Berentsen and I.J.M De Boer

Animal Production Systems group, Wageningen University

# Dairy sector - developments past years

Larger herd sizes

Higher milk yield/cow

More use of automatic milking systems (AMS)

# Current situation summer period

day and night grazing  
**16%**  
(of Dutch dairy cows)

day grazing  
**54%**

zero-grazing  
**30%**

# Recent changes in legislation

Milk quota abolishment

Phosphate ( $P_2O_5$ ) excretion limits

$P_2O_5$  surplus removal

# Objective

To analyse the labour income and greenhouse gas emissions of Dutch dairy farms in a post-quota era

# Modelling dairy farms **with AMS for 2020**

## Dairy farm model with relevant activities and constraints

day and night grazing

day grazing

zero-grazing

linear programming – maximise labour income

Labour income in €/year

Greenhouse gas emissions (GHG) in CO<sub>2</sub>-eq:

CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O

# Activities

*For example*

## On-farm feed production

- Fresh grass → only in summer
- Grass silage
- Maize silage

\*Grass yield dependent on nitrogen (N) application: 100-500 kg

## Feed purchases

- Concentrates → 3 levels of protein
- Maize silage

# Related constraints

- Dietary requirements
  - Protein
  - Energy → higher when grazing
  - Feed intake capacity
- \*Dependent on milk production
- Capacity machinery
- Labour availability
- Nutrient content manure → N and  $P_2O_5$  balance

# Model assumptions 2020

## Input

## On-farm

## Output

Artificial fertilizer

Field operations

Farmland

Land costs

Feed production

Grass and maize yields

Max. grass intake

Feed

Animal production

Manure

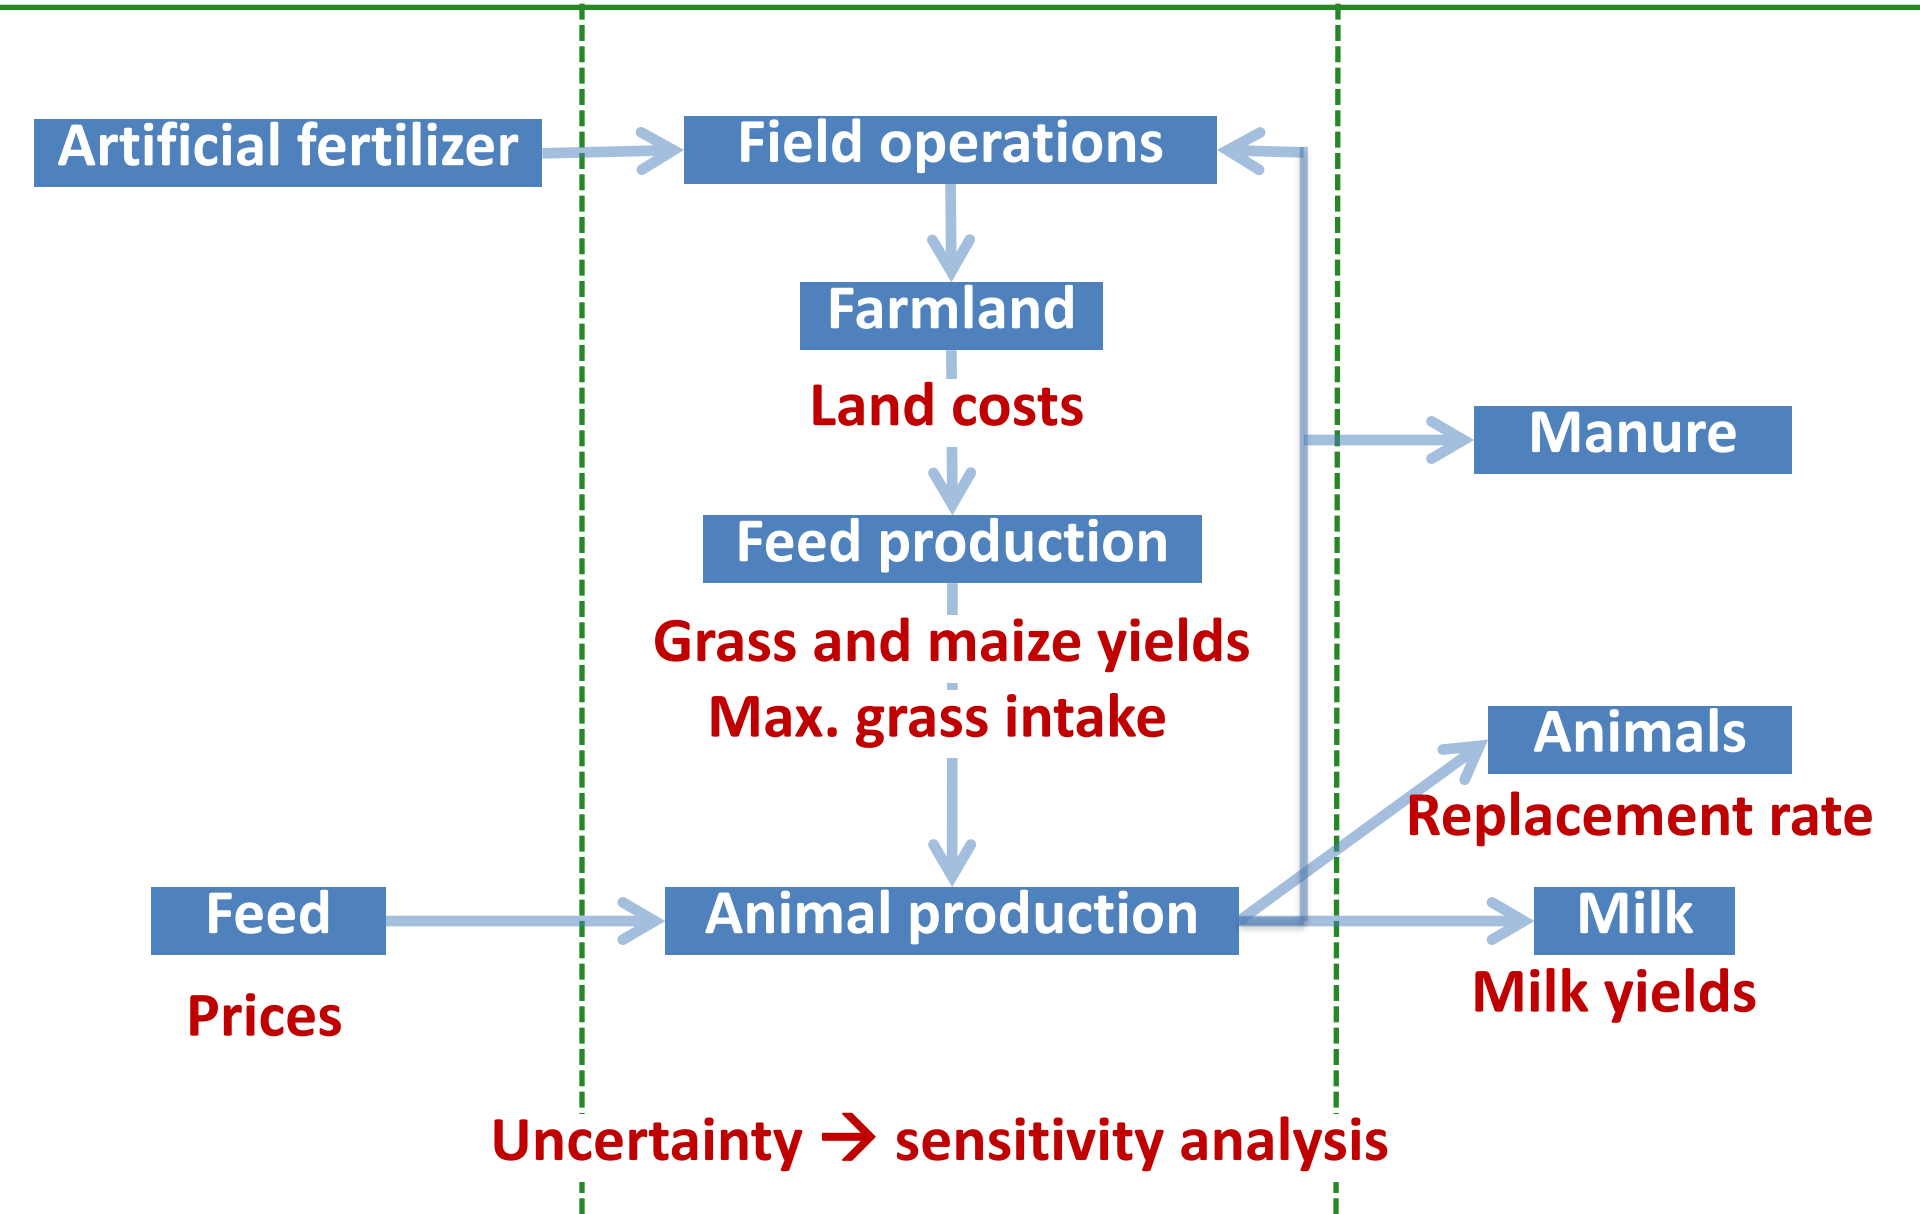

Animals

Replacement rate

Milk

Milk yields

Uncertainty → sensitivity analysis

# Results basic scenario – farm structure

	unit	Day and night grazing	Day grazing	Zero-grazing
<b>Total farmland</b>	ha	64 80% grassland	74	58
<b>Milking cows</b>	n	113	126	123
<b>Farm intensity</b>	kg milk/ha	14,888	15,282	21,208

# Diet composition milking cows

<b>% DM summer</b>	<b>Day and night grazing</b>	<b>Day grazing</b>	<b>Zero-grazing</b>
<b>Grazed grass</b>	75	37	
<b>Grass silage</b>		5	9
<b>Maize silage</b>	21	52	62
<b>Concentrates</b>	4	6	29

<b>% DM winter</b>	<b>Day and night grazing</b>	<b>Day grazing</b>	<b>Zero-grazing</b>
<b>Grass silage</b>	18	23	30
<b>Maize silage</b>	42	49	49
<b>Concentrates</b>	40	28	21

# Labour income in €/year

day and night  
grazing

day grazing

zero-grazing

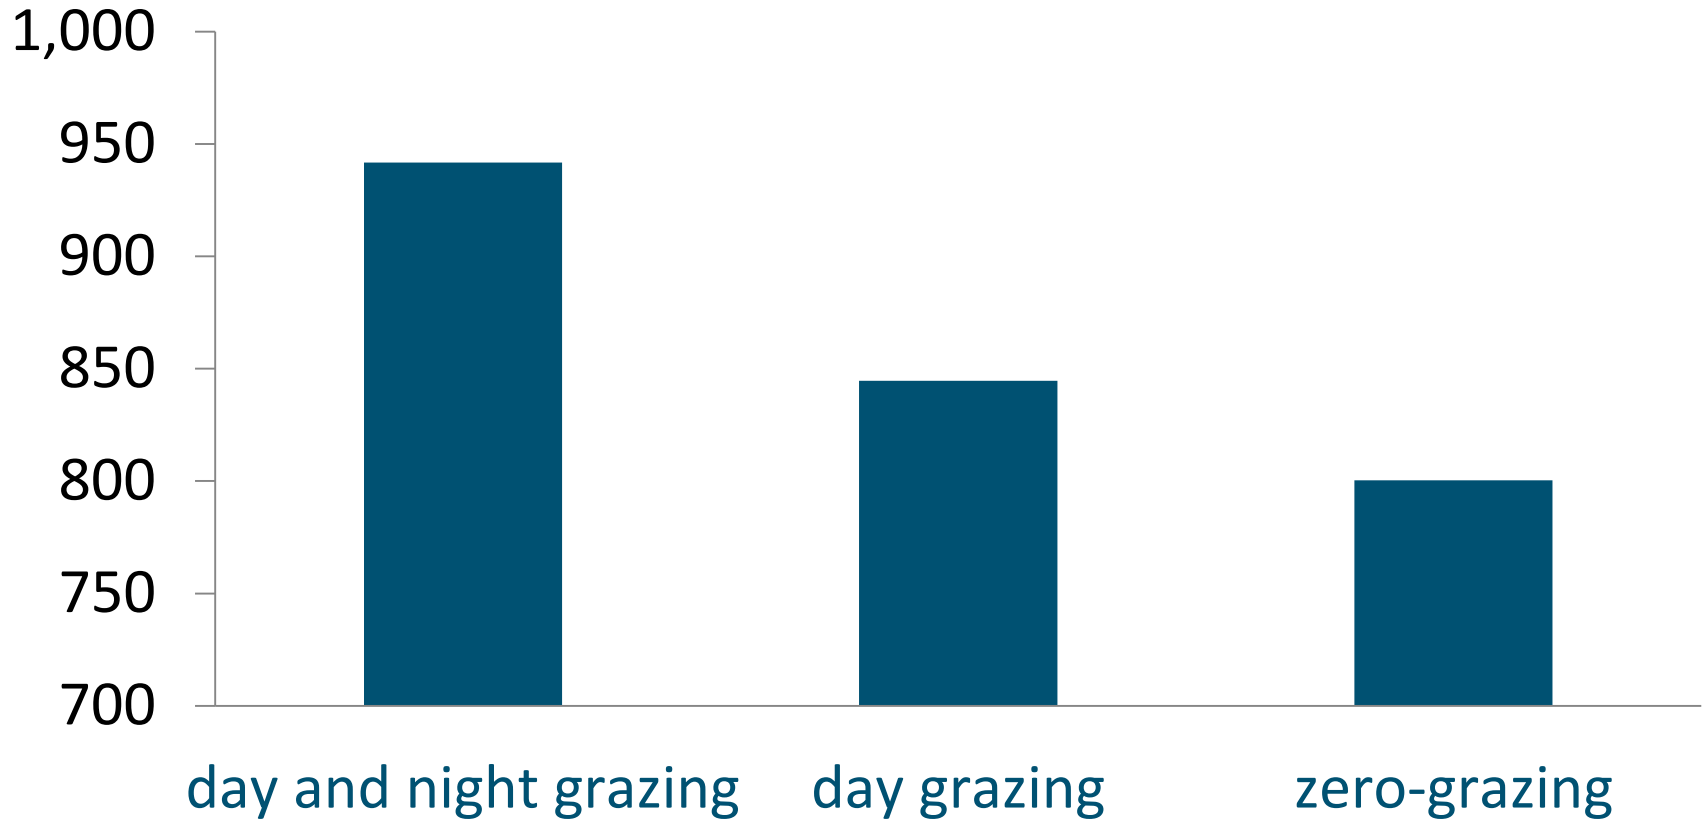

Higher milk revenues

Lower total feed costs

# GHG emissions in CO<sub>2</sub>-eq/t FPCM

Less enteric methane and grassland emissions

# Restrictions in farm size and intensity

## Day and night grazing

- Max. allowed  $P_2O_5$  excretion
- No manure export

## Day grazing

- No roughage purchases

## Zero-grazing

- Max. allowed  $P_2O_5$  excretion

# Sensitivity analysis: influencing factors

All systems: Milk price and **land costs**

## Day and night grazing

- Milk production per cow
- Grazing losses

Grazing systems:  
improvement potential

## Day grazing

- Milk production per cow
- Max. grass into milk (in combi with AMS!)

## Zero-grazing

- Manure removal costs
- Feed prices

# Conclusions

All economically feasible in 2020

**BUT** different vulnerability to different future scenario's

day and night grazing

day grazing

zero-grazing

Economically most attractive

Greenhouse gas emissions in between
