Paratuberculosis (MAP)

Paratuberculosis (MAP) or Johne's disease
= endemic transmissible disease in ruminants due to
Mycobacterium avium subsp. paratuberculosis (Map)

Gut lesions
Rapid weight losses & diarrhea

Economic losses
Negative effects on animal welfare

Paratuberculosis (MAP)

Difficulties to control MAP because

- ✓ **No efficient treatment** available
- ✓ Young animals infected (<6 months) but **long latency period** before first symptoms (after 2-6 years)
- ✓ Tests to detect infected animals (ELISA on blood or PCR on faeces) have a **poor sensitivity** that can be compensated by repeated testing

A better **genetic resistance**
could contribute to control the disease

French PICSAR & PARADIGM projects

2 related on-going projects on integrated control of MAP

PICSAR

INRA

PARADIGM

APIS-GENE and GDS France

Preliminary results

Genomic analysis in cattle

Objectives

Genomic study of confirmed host phenotypes to identify genomic regions (**QTL**) affecting susceptibility to MAP in two dairy cattle breeds

Holstein

Normande

- ➔ Better understand the **genetic determinism** of the susceptibility to MAP
- ➔ Build a first reference population to pave the way for **genomic selection** against the disease

Material & methods: accurate phenotypes

Herds with detected cases enrolled in surveillance program

regular blood **ELISA** + fecal **PCR** tests

Selection of cows in these herds

- 1) With 2 ELISA & 2 PCR tests distant from > 8 months and
- 2) With **clear** and **concordant** negative or positive results, excluding intermediate ones

	Negative	Intermediate	Positive
ELISA IDDEX S/P	< 45	?	≥ 45
PCR ADIAGENE Ct	≥ 40	?	≤ 35

- 3) Controls are negative cows **at least 72 months old** and **born in the same herd and in the same time period** as affected cows

Material & methods: accurate phenotypes

Selection of cows in these herds

***Additional analyses
to confirm phenotypes***
1 ELISA & 1 PCR test

Cows with uncertain
phenotypes removed

Cows with discordant
phenotypes removed

647 CASES
210 Normande
437 Holstein

747 CONTROLS
195 Normande
552 Holstein

Material & methods: genotypes

All the **1,394** cows with phenotypes genotyped with the 50k Beadchip with about 40,000 informative genetic markers distributed over the 29 autosomes (BTA)

405

Normande

NOR

989

Holstein

HOL

~ 60% of the total targeted population in the project

Material & methods: case-control GWAS

Within breed case-control GWAS (Genome Wide Association Study) with GCTA software (Yang et al., 2011)

Each genetic marker tested **one by one**

MAF (Minor Allele Frequency) > 5%

Structure of the population accounted for through a **polygenic effect** of animals, in order to avoid spurious associations

Estimated with a Genomic Relationship Matrix calculated with the markers of the 50K Beadchip

Results: h^2 of resistance to MAP

Heritability h^2

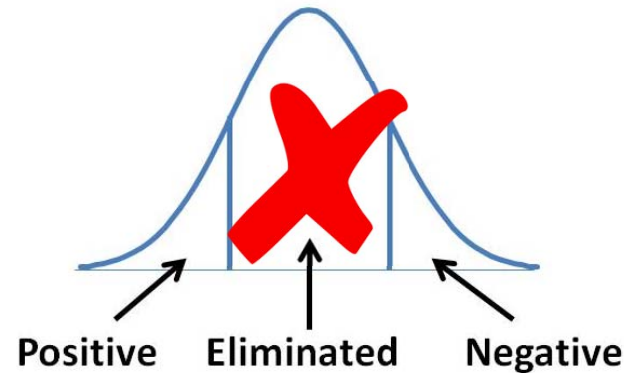

$h^2 = 60\%$

$h^2 = 46\%$

Higher than expected $\sim 30\%$
 \Rightarrow probably due to selection
of phenotypes (elimination
of intermediate phenotypes)

Nevertheless, **genetic variation**
of susceptibility to MAP appears to be **large**

Results: GWAS in Normande

Manhattan Plot at the genome level

p-value = 10^{-6}

p-value = 10^{-4}

Normande = Q-Q plot of GWAS p-values

Results: GWAS in Holstein

Manhattan Plot at the genome level

p-value = 10^{-6}

p-value = 10^{-4}

Holstein = Q-Q plot of GWAS p-values

GWAS results: the most significant QTL

Manhattan Plot on one chromosome

The most significant QTL is located at 70Mb in HOL (p-value = 2.10^{-8})

Zoom on chromosome 12 in 2 breeds

ABCC4 gene
(Crohn's disease)

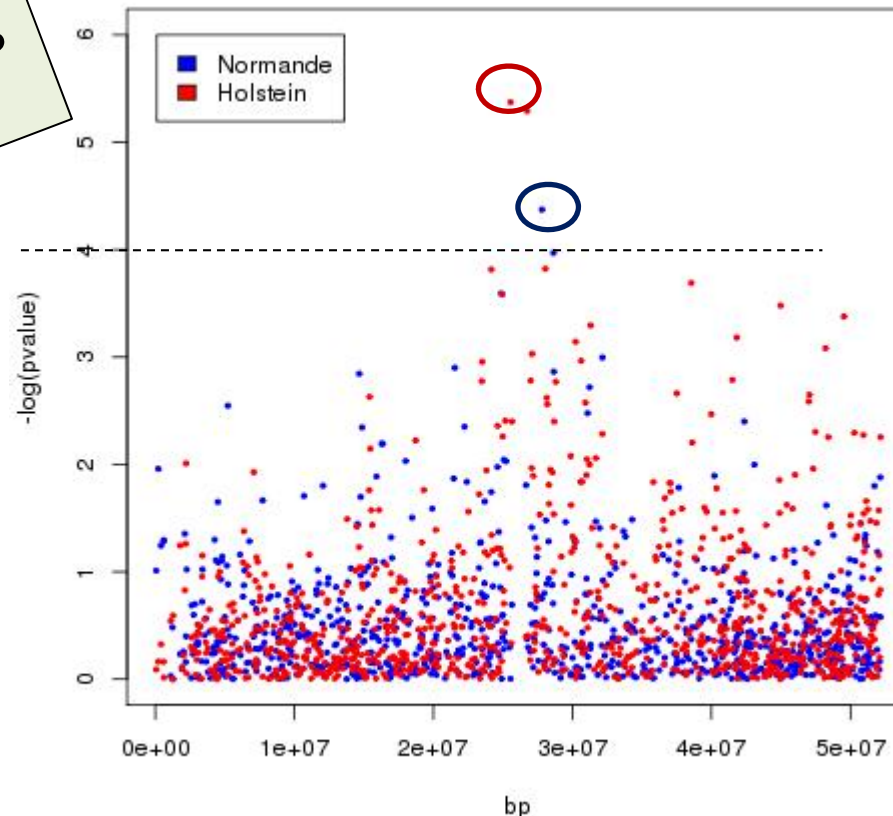

→ 1 QTL at 70 Mb in Holstein (Minozzi et al., 2012)

GWAS results: a QTL shared between breeds

A QTL found in both breeds located at 27Mb in the **MHC region** ($4.10^{-6} < p\text{-value} < 4.10^{-5}$)

Zoom on chromosome 23 in 2 breeds

- ➔ 1 QTL at 32 Mb in Holstein (Minozzi et al., 2012)
- ➔ 1 QTL at 27 Mb in Jersey (Zare et al., 2014)

GWAS results: QTL previously described

$7.10^{-5} < p\text{-value} < 10^{-4}$
