

The impact of the rumen microbiome on the detailed milk fatty acid profile in Danish Holstein

A.J. Buitenhuis, N.A. Poulsen, S.J. Noel,
D.F. Plichta and J. Lassen

Introduction

- **What factors influence the milk composition**
 - Focus on milk fatty acids

Feed

Introduction

Data

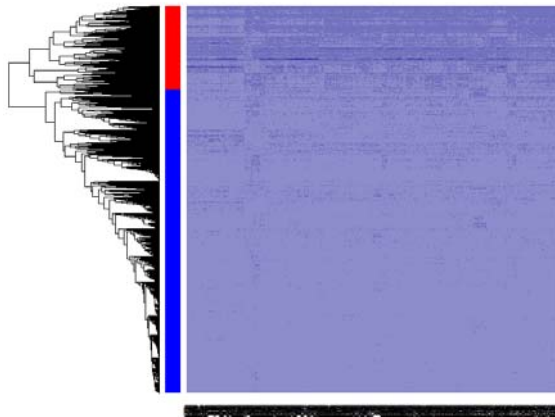

- **292 cows from 3 herds, 1-3 parity, 3-398 DIM**
- **50k bovine SNP information**
- **Morning milk sample → detailed milk fatty acid profile (Gass Chromatochraphy)**
- **Rumen sample → sequenced using 16S approach**

Results: Rumen data

- 8,515 bacterial and 168 archeal OTU's detected

Center scale the data and perform a hierarchical clustering

Bacteria

CI1: 402 OTU's

Results: fatty acids

Hierarchical clustering of the fatty acids:
Extremes are separated into
saturated FA or unsaturated FA

Influence of bacterial cl1 on fatty acids

- Made a genomic relationship matrix based on 50K SNP data
- Made a bacterial relationship matrix based on bacterial cl1 (402 OTU's)
- $Y_{ijk} = \mu + \text{herd}_j + \text{parity}_k + b_1 * \text{DIM}_i + b_2 * e^{-0.05 * \text{DIM}_i} + B_i + G_i + e_{ijk}$
- $h_B = V_B / (V_B + V_G + V_e)$

Results: Influence of bacterial c11 on fatty acids

- SE were relative large, but it was shown that:

Saturated FA

- C6:0
- C8:0
- C10:0
- C12:0
- C16:0

h_B close to 0

Unsaturated FA

- C18:1n11t
- C18:2n6c
- C18:3n3
- CLA

$h_B > 0.50$

Conclusion

- **Necessary to reduce the number of rumen bacteria before making a relationship matrix**
- **Rumen bacteria explain the largest variance of the unsaturated fatty acids**
