Introduction

What is ketosis?

Energy balance (MJ/ day)

Positive

Negative

Ketosis is a metabolic disorder in which the body has to derive energy from ketone bodies

BHB = β -hydroxybutyrate and is a very stable 'ketone body'

NEFA = Non-esterified fatty acids and a measure of fat mobilisation

BHB mmol/l

Sub clinical ketosis

Healthy

Clinical ketosis

NEFA mmol/l

Excessive fat mobilisation

Healthy

Severe mobilisation

BHB mmol/l

Sub clinical ketosis

Can impact milk production,
cow health and fertility

NEFA mmol/l

Heritability

Both BHB and NEFA are heritable

Estimates of 0.06 - 0.40 for BHB and 0.08 - 0.35 for NEFA (Koeck et al. 2014, Oikonomou et al., 2008, Jamrozik et al., 2016).

Incidence

Nationally SCK of c. 30% (Macrae et al. 2012)

BHB mmol/l

Sub clinical ketosis

> 3 mmol/l

Clinical ketosis

NEFA mmol/l

Excessive fat mobilisation

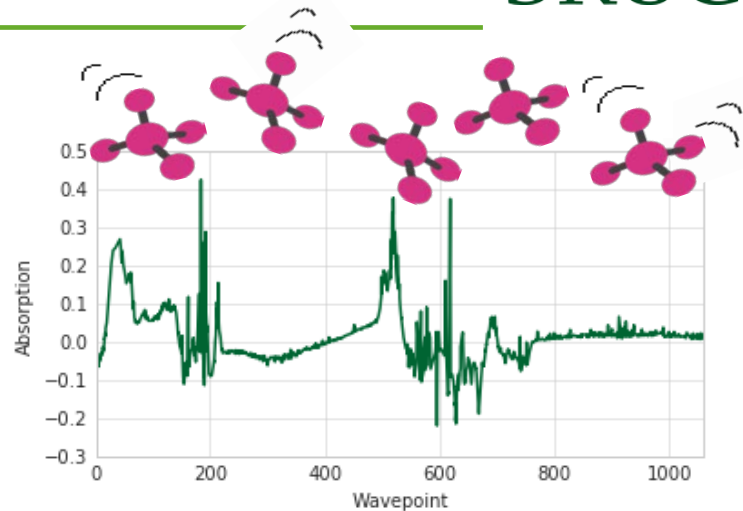

Severe mobilisation

Sub clinical ketosis

Can impact milk production, cow health and fertility

Clinical ketosis

Loss of appetite, reduced milk yield, can induce hypoglycaemia, hyperketonaemia, immunosuppression

Objective : Can we detect levels of BHB and NEFA from milk MIR spectra?

Materials & Methods

Alignment & calibration

Partial Least Squares Analysis

Predicted *NEFA*

Validation

Fatty acids (Soyeurt et al., 2011)

Energy traits (McParland et al., 2011)

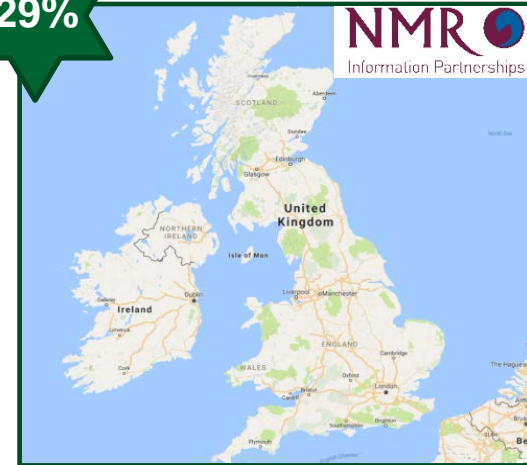

56%

14%

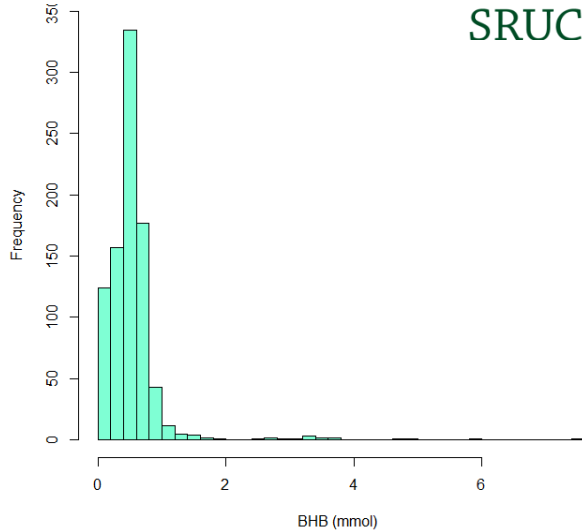

29%

- Spectral data standardised in accordance with Grelet et al., 2016. as part of the Optimir project.
- Transformation of reference data
- Data thinning (similar to Grelet et al. 2016)
- Restrictions on residuals in defining outliers
- Feedback from receiver operating characteristic curves (sensitivity and specificity, area under the curve)
- Inclusion of various phenotypic traits alongside spectral data in the PLS
- Optimal number of factors to use in the model according to SAS

- Converged upon a tool
 - Using data from all sources
 - Residuals > 2 stdev of the global press considered outliers and removed
 - Both traits (natural) log transformed
- Split sample validation
- R = square root of the coefficient of determination

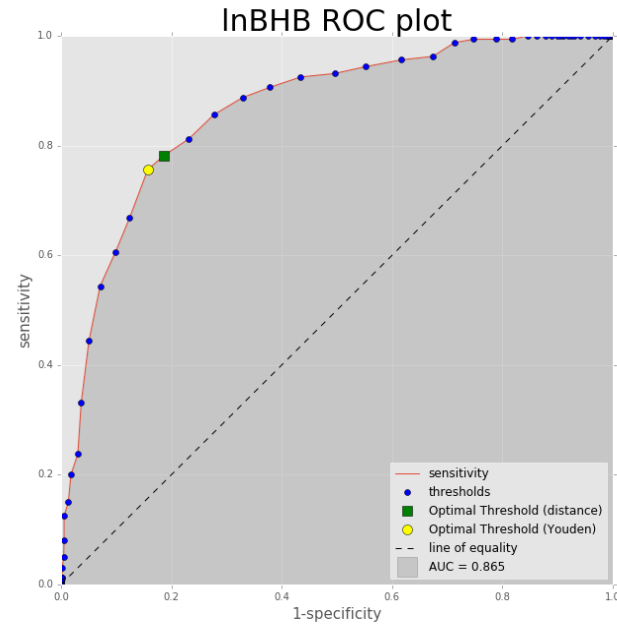

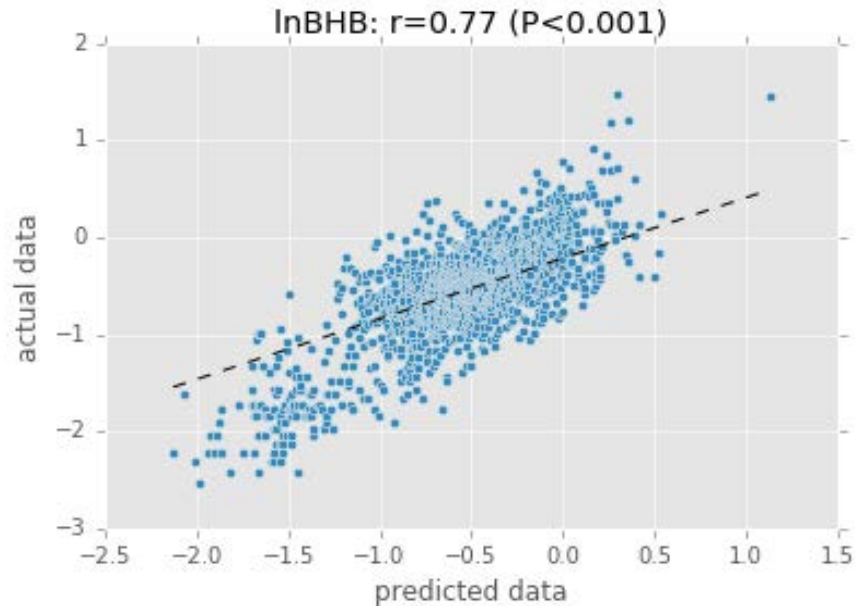

$N = 1449$
 $R = 0.81$

$N = 1443$
 $R = 0.84$

Results

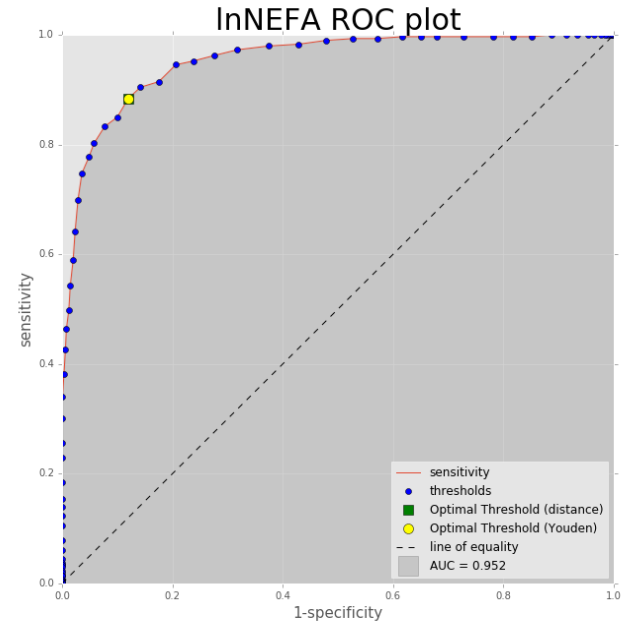

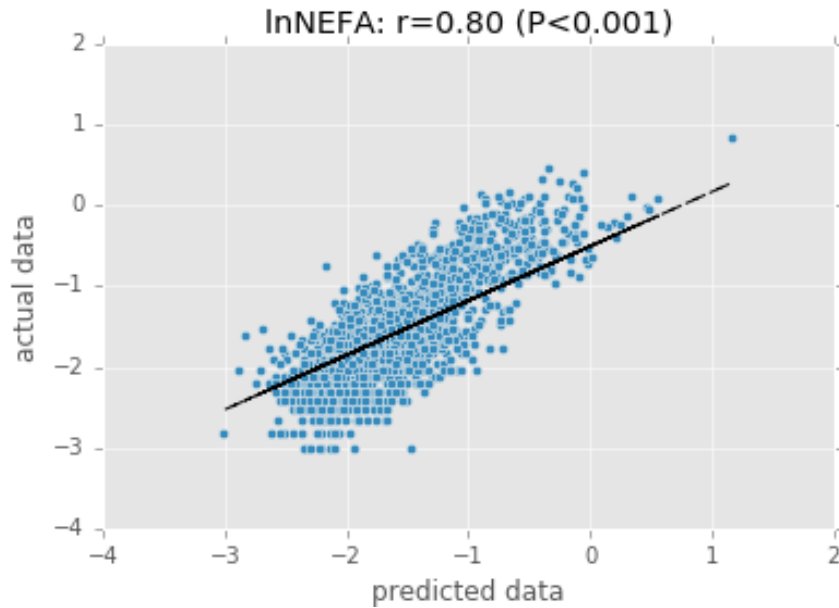

4 way cross validation

RPD = 1.27
SEC = 0.4
SDEP = 0.35

Results

4 way cross validation

Area under
the curve =
0.95

RPD = 0.81
SEC = 0.48
SDEP = 0.71

Avg. predicted InBHB by lactation and DIM

Avg. predicted InBHB by lactation and DIM

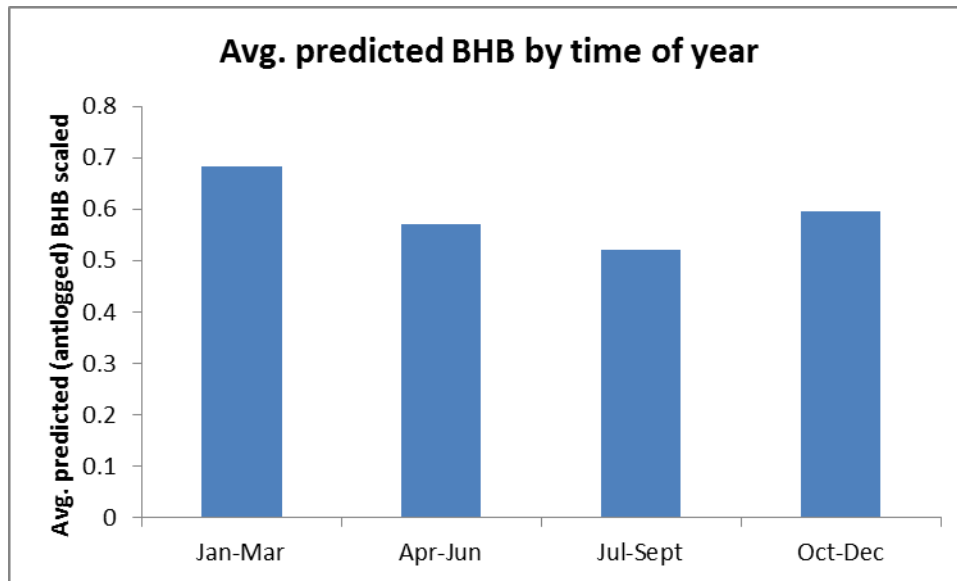

Predictions from 366 herds, >150,000 animals and almost 2 million animal testdates

Avg. predicted InBHB by lactation and DIM

Predictions from 366 herds, >150,000 animals and almost 2 million animal testdates

-
- Demonstrated the ability to predict BHB and NEFA using MIR
 - Could be used routinely as an early-indicator of potential health issues
 - Energy balance predicted routinely from MIR at NMR; BHB and NEFA predictions due to accompany these

Acknowledgements

This work was funded by Innovate UK, BBSRC and the Scottish Government. This was completed with project partners National Milk Records, UK, who undertook the MIR analysis of the milk samples, and Marks and Spencer's.

Procedures for managing spectral data came from collaboration with the Optimir project. Thanks to Tomasz Krzyzelewski and Ian Archibald for maintaining the national databases at SRUC and Scott Denholm for help with the

ROC plots.
