## INTRODUCTION

Little is known regarding the effects of feeding reconstituted vs. dry alfalfa hay to dairy calves on health criteria. Twenty neonate Holstein male calves were used to investigate the effect of feeding reconstituted vs. dry alfalfa hay on health status.

The aim of the present study was to evaluate the effects of feeding starter feed containing dry (AH) vs reconstituted (RAH) alfalfa hay at 10% of dietary dry matter on health status of calves during the pre-weaning period.

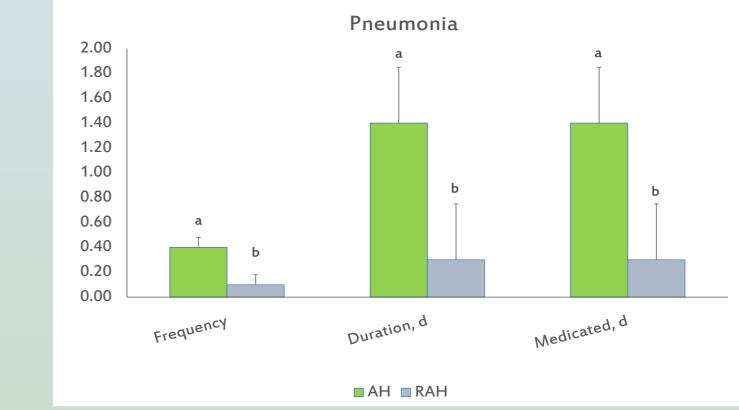

Health status monitored several times daily Respiratory score Scale from 1 (normal) to 5 (wet cough)

Diarrhea

Fecal score 23

Calves were offered milk at 6 L/d from d 3 to d 43, 4 L/d from d 44 to d 46, and 2 L/d from d 47 to d 49 of age. Hay was reconstituted with water 24 h before Feeding.

METHODS

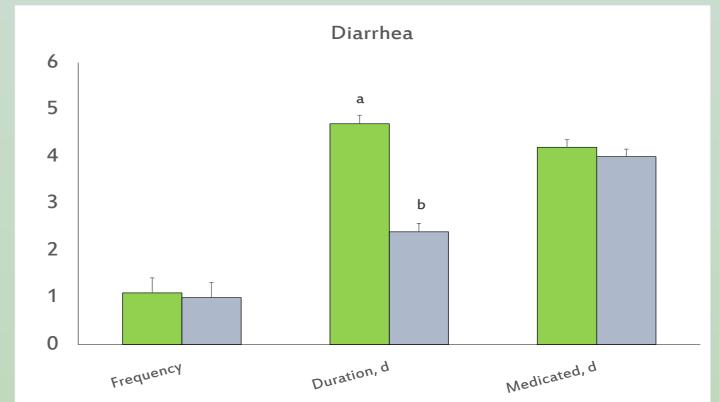

Figure 1. Poisson regression for frequency and duration of pneumonia and days medicated during the preweaning (d 1 to 49) period as influenced by feeding dry- (AH) vs. reconstituted alfalfa hay (RAH) to Holstein dairy calves.

Figure 2. Poisson regression for frequency and duration of diarrhea ( $\geq$  3), and days medicated during the preweaning (d 1 to 49) period as influenced by feeding dry- (AH) vs. reconstituted alfalfa hay (RAH) to Holstein dairy calves.

Health scores were recorded once daily

Pneumonia Respiratory score >1

<u>Statistical analysis:</u> Models for occurrence of diarrhea, respiratory illness and needs for medication by logistic regression using a binomial distribution in the GLIMMIX procedure in SAS were evaluated. Frequency and duration of diarrhea, respiratory illness and administration of medication with a Poisson distribution using the GENMOD procedure of SAS were tested.

"Where 1 = normal; 2 = soft to loose; 3 = loose to watery; 4 = watery, mucous, and slightly bloody; and 5 = watery, mucous, and bloody.

<sup>2</sup>The odds ratio (OR) indicates the probability of either having diarrhea (≥ 3), pneumonia, or needing medication for the AH vs. RAH diet. If the OR is > 1, the AH diet in the comparison is more likely to have diarrhea (≥ 3), pneumonia or to be medicated than the RAH diet by a factor of the difference above 1. If the OR is < 1, the AH diet has a lower probability of occurrence than the RAH diet.

Feeding RAH improves health status through decreasing the occurrence of diarrhea and respiratory illness.
