Problem definition and objective

Modern pig farmers desire easy to manage and economically efficient animals. Drivers for this trend are globalization, climate change and an increased public concern in animal health and welfare.

Breeding more viable and robust pigs can offer a solution. However, selection is usually restricted to sow lines.

This research investigated the option of selecting on terminal Pietrain boar lines to improve the vitality of crossbred offspring via commercial farm management data.

Results

1. Vitality scores have a low to intermediate heritability (11,0%).
2. No adverse genetic correlations between vitality scores and reproduction parameters were observed.
3. Changing the genetic standard deviation (σ_a) of vitality one unit upwards, improves the mean vitality with 7,9% (Genetic Coefficient of Variation; GCV).
4. The genetic sire effect was responsible for 24,1% of the explained variance. Substantial genetic progress can be made by selection on terminal Pietrain boars.

Genetic parameter	Vitality score	TNBA	NBD
h^2 (hpd)	11,0% (2,7-19,3)	6,5% (1,1-12,2)	14,2% (7,2-21,4)
% Explained variance sire	24,1%	8,8%	14,5%
GCV (hpd)	7,9% (3,9-10,5)	6,2% (2,5-8,5)	4,3% (3,1-5,3)

Table 1. Genetic parameters of the investigated traits vitality score, Total Number Born Alive (TNBA) and total Number Born Dead (NBD). Heritability (h^2) and Genetic Coefficient of Variation (GCV) are given with 95% highest posterior density (hpd) values between brackets.

Conclusions

Selection in terminal boar lines has a great potential to improve pig vitality

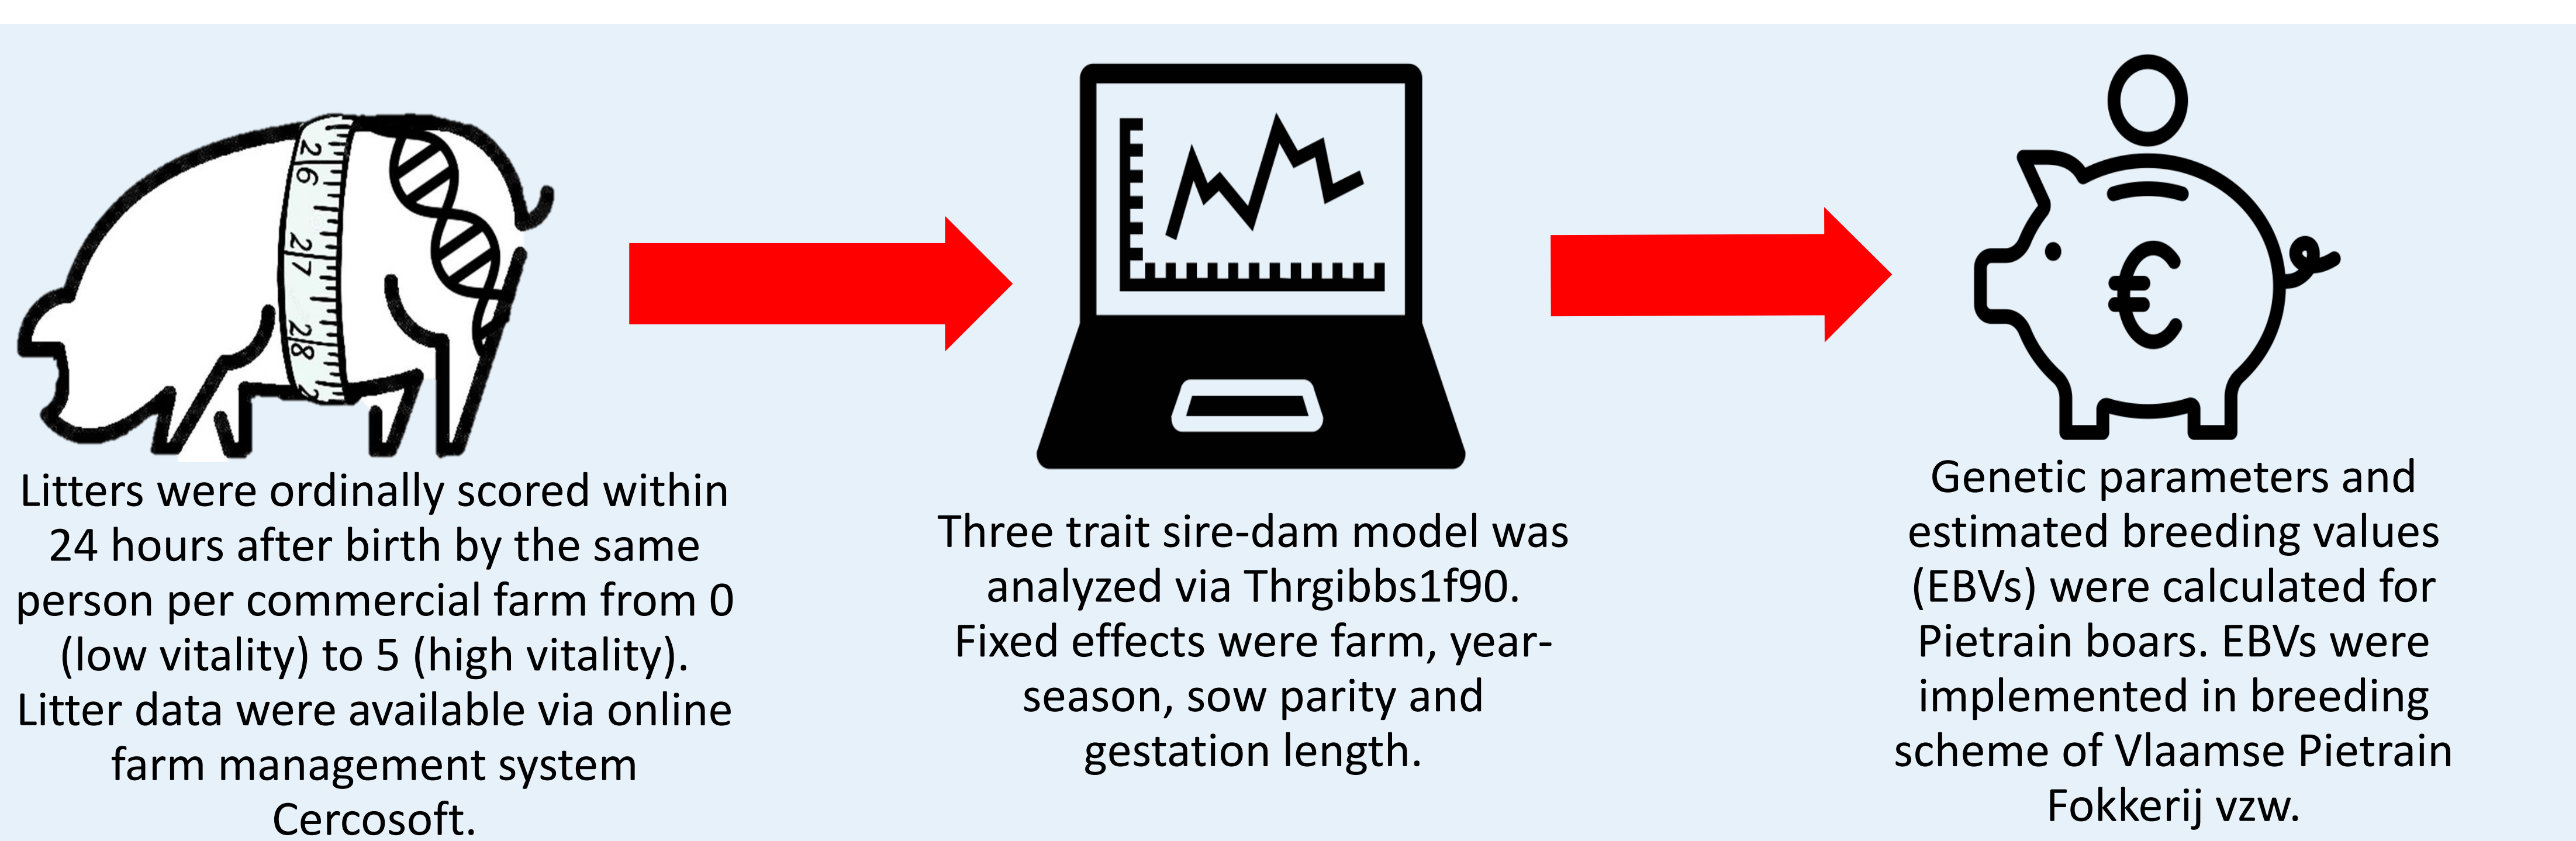

Commercial farm management data are abundantly available and can be implemented in breeding programs

Dataset	
Scored litters	5937
Period	January 2016 – May 2018
Pig farms	6
Pietrain boars	732
Commercial sows	2708

Table 2. Metrics of the used dataset. A full pedigree (up to 15 generations) was available for Pietrain boars. For commercial sows, pedigree was available up to 2 generations.
