

Application of genomics in breeding schemes for the genetic improvement of sheep and goats

Learning from our experience in Australia

Daniel Brown

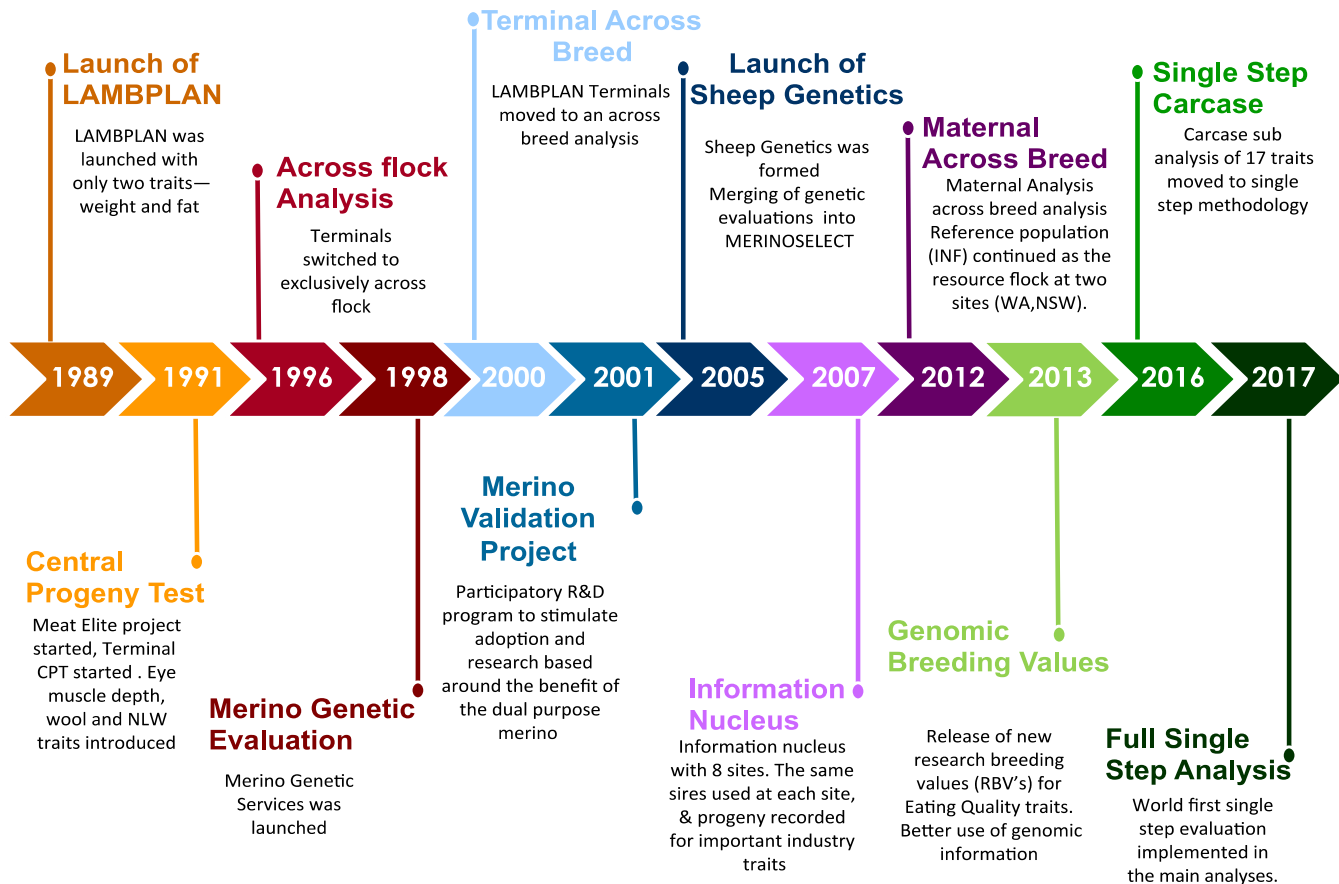

Andrew Swan, Vincent Boerner, Li Li, Phillip Gurman,
Aaron McMillan, Julius van der Werf, Hamish
Chandler, Bruce Tier & Rob Banks

Outline

- Evolution of breeding values in Australia
- Genomic reference population
- Linkage
- Value of information sources
- Key technical challenges
- Validation of benefits
- Breeding tools

Evolution of Sheep Genetics genetic evaluation

Single Step Australian Sheep Breeding Values (ASBVs)

Animal performance

Resource flocks and ram breeders

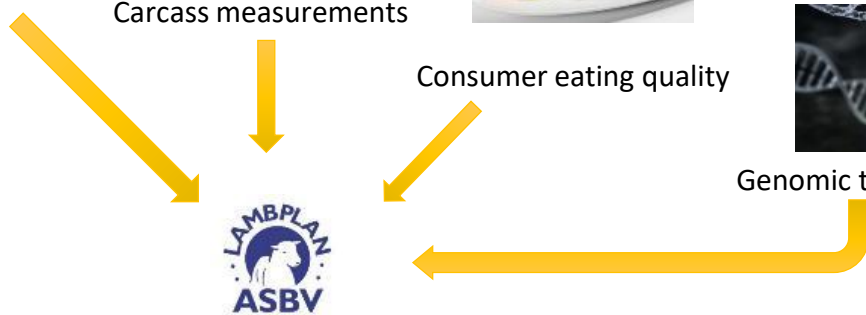

Carcass measurements

Consumer eating quality

Genomic testing

The multi-breed nature of Australian sheep

Three “breed groups” each with separate genetic evaluations (2M+ animals)

Fine wool

Medium wool

Strong wool

Border
Leicester

Coopworth

Composites

Poll Dorset

White Suffolk

Texel, ...

Composite breeding is increasing

Trend in Breed Composition

Maternal Breeds Terminal Sire Breeds

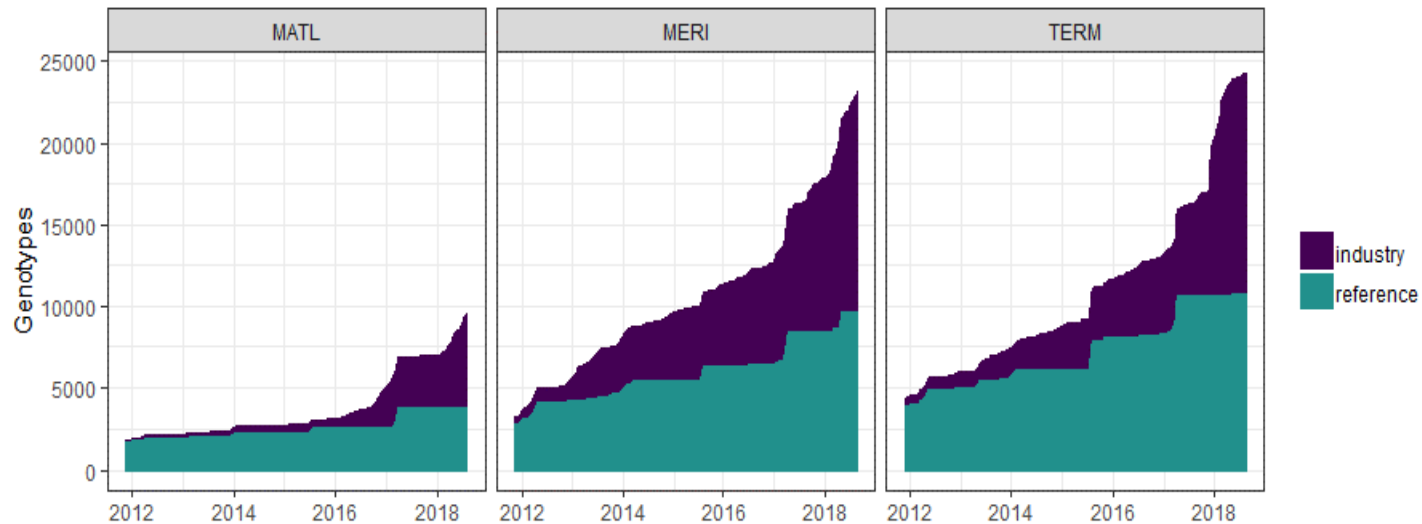

Scale of our Sheep Genetics evaluations (Aug 2018)

	Merino	Maternal	Terminal
Pedigree	2.5M	2.1M	2.9M
Records	13.6M	5.1M	8.8M
Flocks	510	324	929
Av Flock size	460	358	210
Traits	76	46	45
Genetic groups	558	104	94
Genotypes	24K	7K	22K
% current drop	1.1%	0.5%	1.5%
Solver time (hrs)	13.2	3.5	6

Number of genotyped sheep in the genetic evaluation

Animal Group	Breed Analysis			Total
	Maternal	Merino	Terminal	
Industry progeny	5,014	15,175	10,782	30,971
Industry sires	612	2,120	2,642	5,374
Resource flock progeny	4,875	13,407	11,671	29,953
Total	10,501	30,702	25,095	66,298

Trends in genotyping

The Genomic Reference Population

Reference population design (INF 2007 – 2012)

- Eight sites across Australia
- Mostly Merino ewe base
- 100 sires mated annually
 - 40 Merino
 - 40 Terminal
 - 20 Maternal
- Comprehensive phenotyping of progeny
- 50K SNP genotypes + (15K, HD, Seq)

Reference population post 2012 (MLA Resource Flock)

- Two of the eight original sites (Armidale and Katanning)
- Focus on carcass and eating quality traits
- Of the other trait groups, reproduction is our biggest limitation:
 - Commenced genotyping recorded ewes in industry flocks to boost the repro reference → still need to boost numbers
- Exploring alternate structures to work with industry based flocks

Genetic linkage between flocks

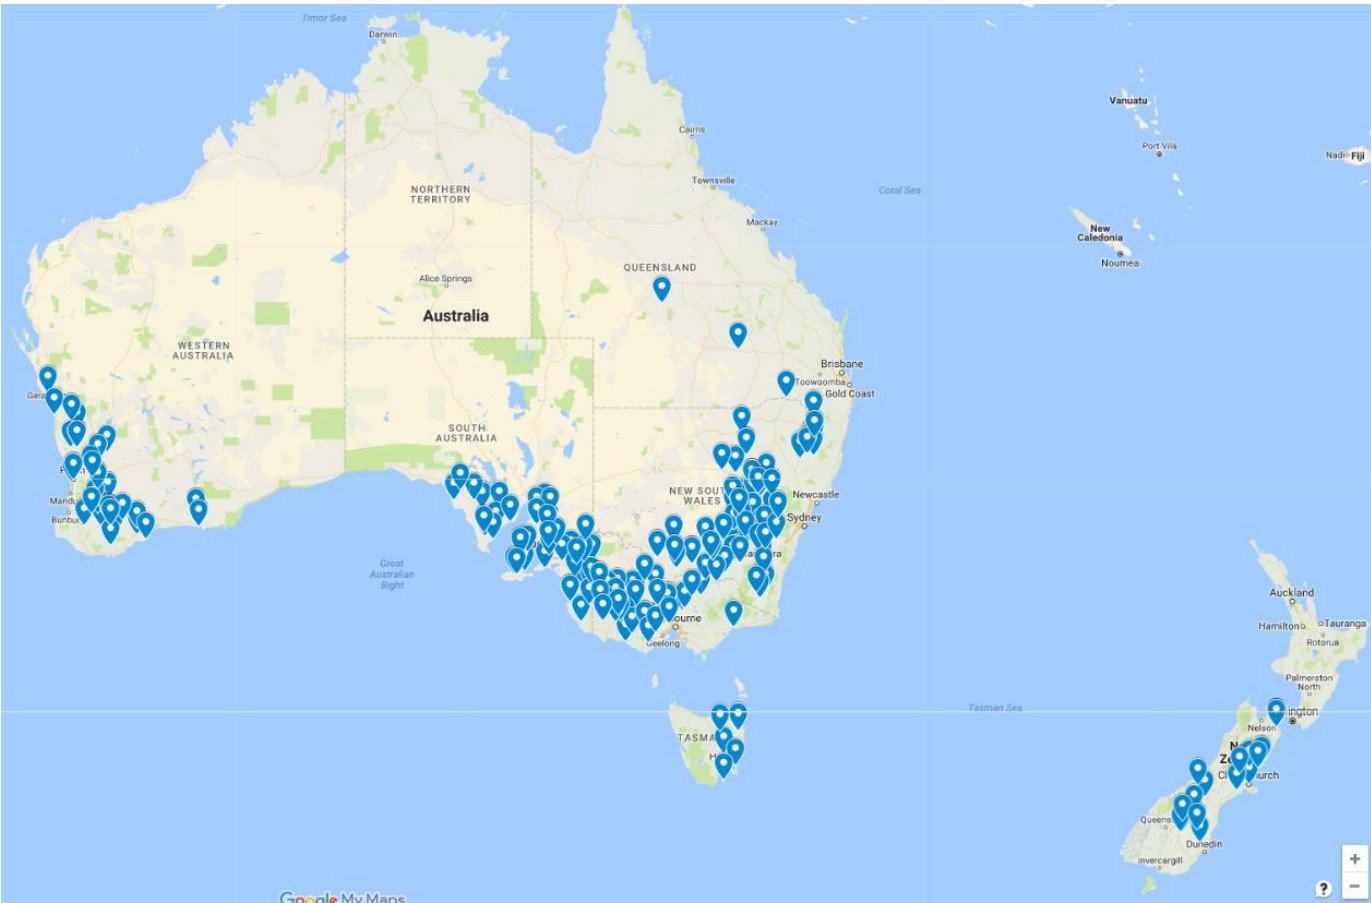

Strategies for generating linkage

- Using sires from other flocks
- Entering sires into;
 - Resource flock
 - Sire evaluations
- Young sire programs / performance groups
- Dams and decedents or link sires help
- Need to be performance recorded for key traits
- Linkage need for all breeds, flock, years and groups
- Genomic testing will help

Flock x Flock genetic linkage

Dispersed Flocks

Genomic Linkage

Accuracy increase with relationship to reference

Average accuracy of yearling fibre diameter for pilot animals by flock

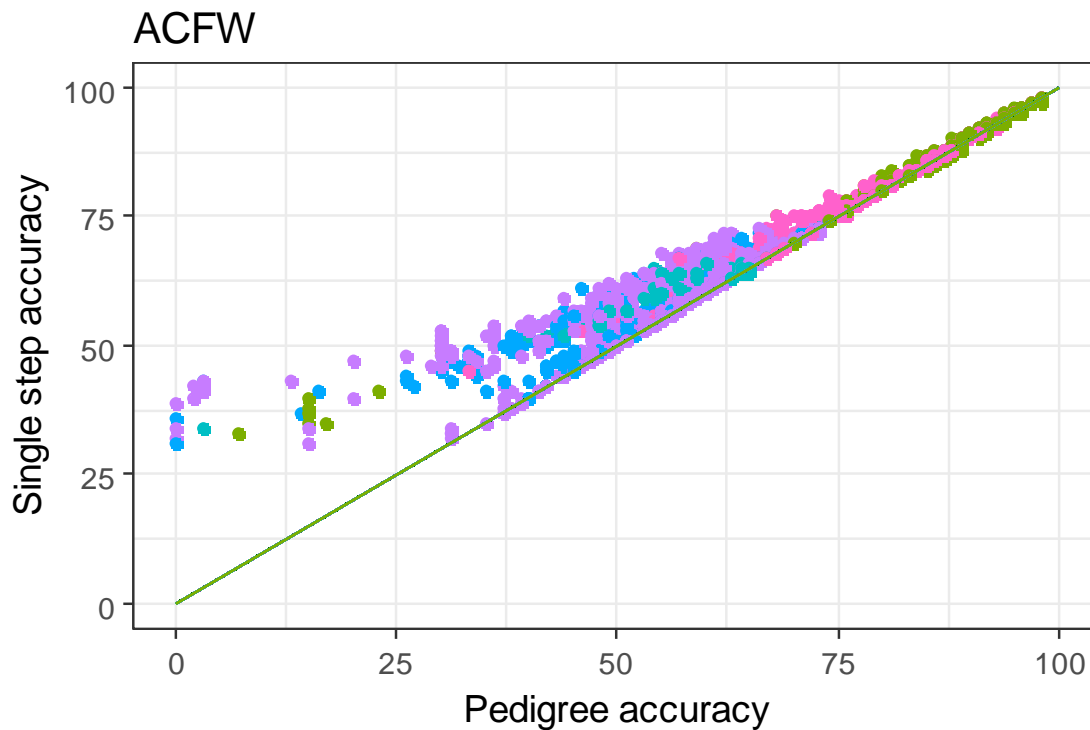

Value of information

Phenotype is still king

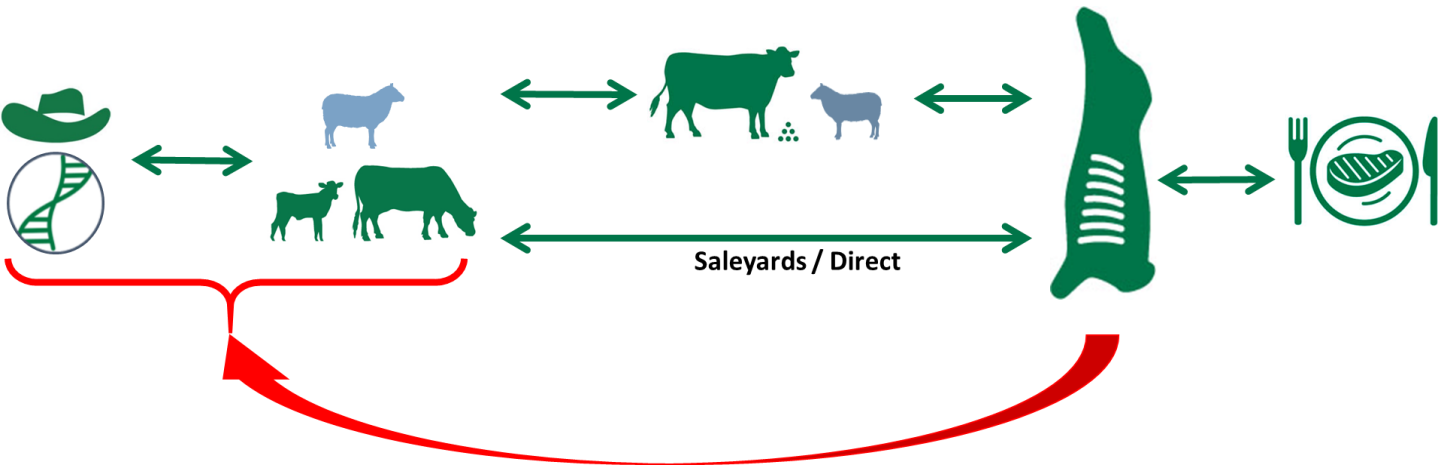

- Breeders seeing more value in;
 - Pedigree
 - Good quality phenotypes
 - Genomic tests
- Value of slaughter info from surplus ram breeding animals and progeny tests

Value of genotyping

Genomic selection most beneficial when EBV accuracy is low

ALMTech: Advanced Livestock Measurement Technologies

Superiority of top 10% selected on Carcass+ and EQ

Merino example: Relative responses

Relative to Basic scenario

Scenario	Pheno	+Geno	+Short GL
WWT	35	66	76
Basic	100	111	125
Plus	111	119	135
NLW	126	133	151

Relative to NLW scenario

Scenario	Pheno	+Geno	+Short GL
WWT	27	52	60
Basic	79	88	99
Plus	88	95	107
NLW	100	106	120

- Massive improvement in gains by recording key Breeding Objective traits
- 5-10% increase in gain from genotyping alone
- 20-25% increase in gain if genotyping is combined with earlier joining
- 60% of gain from just a wwt, genotype and shorter GL
- Cost:benefit?

Technical Challenges

SS-GBLUP model

- H-1 matrix with G calculated ala Yang
 - allele frequencies across all genotypes within breed group

$$\mathbf{H}^{-1} = \mathbf{A}^{-1} + \begin{pmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{G}^{-1} - \mathbf{A}^{-1}_{22} \end{pmatrix}$$

- Genetic groups fitted explicitly

- Lambda

$$\mathbf{G} = \lambda \mathbf{G}_m + (1 - \lambda) \mathbf{A}_{22}$$

- Accuracies as per Li *et al* (2017)
AAABG

Lamba influences many aspects of EBVs

- Accuracy
 - Average correlation between adjusted phenotype and SS-EBV

A weight of 0.5 is being used in genomic evaluations for sheep as a compromise between accuracy and bias across traits and breeds.

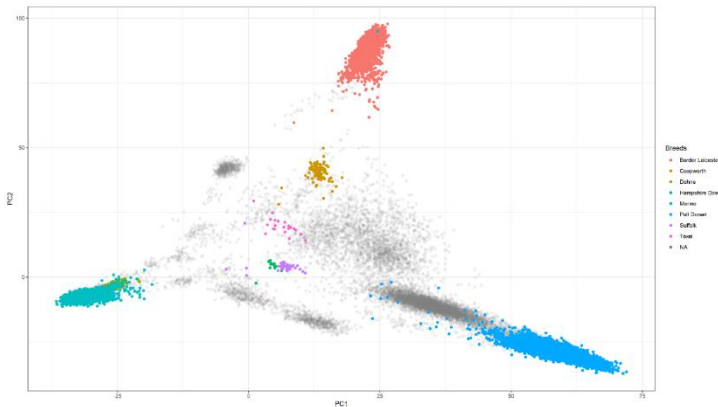

- Genetic Trends

Breeds via GRM

Genotypes show breed structure

- Account for breed structure in H^{-1} :
 - Breed specific frequencies versus meta-founders?
- Obtaining sufficient genotypes to define a breed is a challenge
- Composites with missing parent breeds

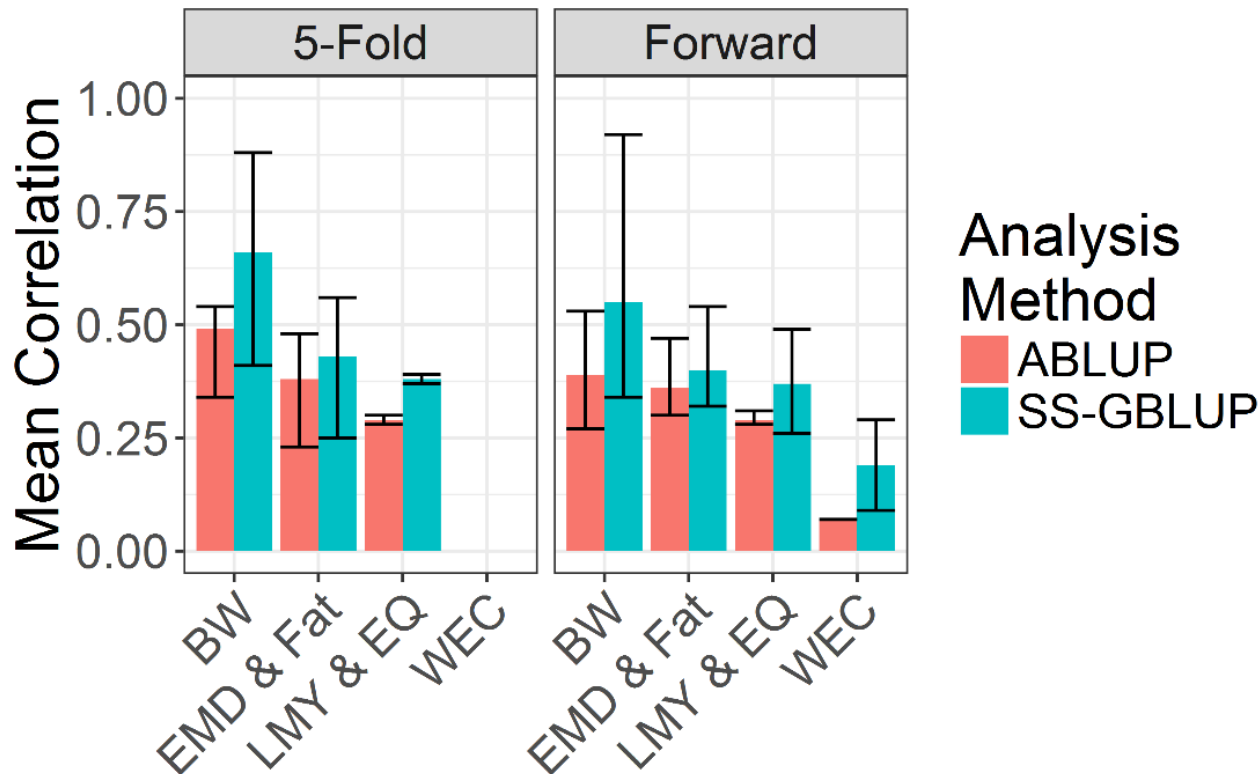

Building the Multi-breed GRM

Validation

SS-GBLUP provides increased predictive ability compared to ABLUP

Genomic predictions for small breeds

- Little or no benefit from across-breed genomic prediction
- Need a relevant reference population for breeds of choice
- Progressive breeders with specialist breeds or composites would like to use genomic information
- But breeders not genotyping because they are not included
- And we don't include them because there are not enough!

Small breed validations

- Including genotypes from small breeds improves empirical prediction accuracy by small amounts
- Accuracy improvements of SS versus pedigree EBVs are less than observed for the major breeds
- No impact on EBVs of animals from the main genotyping breeds (min $r = 0.99$)
- More impact from multi-breed G (min $r = 0.97$), but good reasons to use it

Inclusion of genotypes from small breeds needs qualification of benefits and advice on investment in reference populations

RAMping Up Genetic Gain

RAMping Up Genetic Gain

Flock based reports on three broad categories;

- Data Quality
 - Influences accuracy of selection
- Average sire & dam age
 - Indication of generation interval
- How well ASBVs are used to make selection decisions
 - As close as we can get to selection intensity

Genetic Progress

Impact on industry (genetic gain - index points/year)

- Summary of genetic progress since 2011
- 33 Terminal flocks with significant numbers of genotypes over last 5 years

	2000-2010	2011-2017	
Terminals (LEQ)	1.36	2.00	+47%
Terminals (C+)	3.85	4.29	+11%
Merinos (MP+)	1.57	2.19	+39%

Confounded with;

- Index development
- Genetic parameters (r_g)
- Industry awareness
- Reference population

Conclusions

- Single step analysis fully implemented
- Process of continual improvement
 - Traits
 - Models
 - Computational capacity
- Working with industry on breeding program design
