Introduction

Nowadays, donkeys and mules are essential for transportation in poor, arid, and rough regions around the world although, in developed countries, this pack animal is no longer required. As a consequence, not only individual breeds are endangered, but also the whole species is heading for extinction. One of the first stages in conservation program of endangered breeds is the evaluation of their genetic variability.

In this study we propose a multiplex PCR including a set of 22 microsatellite markers (AHT4, AHT5, ASB23, COR112, COR214, HMS2, HMS3, HMS5, HMS6, HMS7, HMS18, HTG6, HTG7, HTG10, HTG15, LEX27, LEX33, TKY297, THY312, TKY321, UCDEQ(CA)425 and VHL20), specifically designed for donkey, to be co-amplified simultaneously in a multiplex PCR. Primers sequences were re-designed to achieve a final configuration allowing all markers to be analyzed together.

The proposed microsatellites were all well-amplified in donkey samples and all of the microsatellites used in this study were amplified and were polymorphic in blood samples of domestic donkey breeds.

DNA Donkey Comparison Test 2016-2017 organized by International Society for Animal Genetics (ISAG) included these markers and propose a standardized nomenclature.

The mean allele number for the microsatellites included in the proposed panel is 5.70 using a small number of samples. The cumulative probability of exclusion reached 99.9997725%. This donkey-22plex PCR panel can be used for genetic characterization, parentage verification and individual identification.

Material & Methods

Sample Processing: Whole blood was collected in tubes containing Magic Buffer® or EDTA. Blood sampling was carried out by *Tecan® Genesis Freedom* allowing sample aliquoting and barcode reading.

DNA extraction was performed by BioSprint 96 Blood Kit® of Qiagen® in a 96 format.

PCR were performed with *Qiagen Multiplex PCR Kit*[®] by multipippetors from *Tecan*[®]. Amplification Program: 15' to 95°C; 40 cycles of: 30" to 95°C, 45" to 58°C and 1' to 72°C; 15' to 72°C in a *GeneAmp*[®] 9700 PCR System of Applied Biosystems[®].

PCR products were analyzed with an *ABIPrism 3130xl Genetic Analyzer*[®] from *Applied Biosystems*[®]. Results interpretation was performed by *GeneMapper*[®] software from *Applied Biosystems*[®].

Table 1: Panel of donkey markers. Colors represent the dye used for each marker. It is also included the chromosome number were each one is located if it is known (in horse), allelic range and primer concentration on the PCR *multiplex* mix. Heterozygosity (H), Polymorphic Information Content (PIC) and Probability of Exclusion (PE) set out the usefulness of these markers to carry out paternity analysis. This panel can detect incorrect genealogical relationships with a Global Probability of Exclusion of 99.99977%.

Results

A multiplex PCR reaction, including 22 microsatellites markers, has been designed including most commonly used donkey-specific markers in laboratories around the world and included in the proposed list for the Donkey International Comparison Test 2016-2017 organized by the International Society for Animal Genetics (ISAG) (Table 1). In order to obtain higher probability of exclusion have set a procedure to amplify the largest number of markers as possible in a single PCR reaction. Particular concentration of each primer was very important to obtain a correct amplification of all markers in the multiplex PCR reaction. Robotic procedures were implemented to minimize the risk of genotyping errors and parentage verification mistakes when a large number of samples are analyzed.

All of the microsatellites used in this study were amplified and were polymorphic samples of several domestic donkey breeds.

ISAG proposes to use the same allelic nomenclature, with letters, in horses and donkeys. It is important in mules (the offspring of a male donkey, a jack, and a female horse, a mare) or hinny (the offspring of a male horse, a stallion, and a female donkey, a jenny) were genotypes of horses and donkeys are used in the same paternity analysis.

Some microsatellite markers (COR112 and COR114) show, in some donkey breeds, a mix of even and odds alleles. A correct interpretation of these alleles is important both in genealogical control and genetic characterization studies in order to avoid false compatibilities/incompatibilities or estimate the genetic diversity correctly. A mix of even and odd alleles is a problem when the names of the alleles are letters, this can be solved when numbers are used.

HMS3 is a known microsatellite marker with null o weak amplification alleles in practically all the horse breeds around the world but in the donkey breeds analyzed, until now in this laboratory, this type of allele seems not to be present.

AHT4 shows alleles with a length range longer and shorter that in horses. The smaller allele is called "z" because is smaller than "A" in the allele denomination used internationally in horses.

Discussion

High number of polymorphic markers amplified by PCR reaction is important to obtain a high probability of exclusion on paternity control. The proposed system allows to process a very large number of samples in a short period of time ensuring a accurate reliability and traceability of the obtained results.

Twenty two polymorphic microsatellite donkey-specific are amplified simultaneously in one multiplex PCR reaction. All the markers proposed are polymorphic and can be coamplified in samples of several donkey breeds. This panel of markers can be used routinely for donkey parentage verification and reached and average number of alleles in these markers of 6.7 and a global probability of exclusion of 99.99977%.

The proposed panel of DNA markers can be used in several fields of animal breeding, e.g. examination of genetic structure of populations, estimation of populations inbreeding, maintenance of autochthonous populations, estimation of genetic distance between populations and breeds, as well as planning of crossing programs in endangered breeds.
