Effect of rapeseed fat and saturated fat on milk production and enteric methane, when added to diets with different ratios between grass-clover and maize silage

CHRISTIAN FRIIS BØRSTING, SAMAN LASHKARI & MARIA HOLST KJELDSEN
DEPARTMENT OF ANIMAL AND VETERINARY SCIENCES, Aarhus University, Denmark

BACKGROUND

Dietary fat can reduce enteric methane (CH₄) from ruminants

- > On average ~ 4 % reduction per 10 g increase in fatty acids per kg DM (Niu et al. 2018, Børsting et al., 2020)

 Because (Hellwing et al., 2013)
- > Fat is not fermented in the rumen (~1 % reduction)
- \blacktriangleright H₂ is used during biohydrogenation of unsaturated fat, and therefore does not form methane (~ 0.7 % reduction for rapeseed fat)
- ➤ Alters microbial fermentation of fiber (~2 % reduction depending on fat source)

To reduce enteric methane from 2025 it is mandatory in Denmark to

- > To feed 60 mg 3-NOP (Bovaer) per kg DM during 3 month per year for non-organic dairy cows
- Or feed at least 48 g fatty acids per kg DM to non-organic dairy cows year round
 - > This is 15 g more than in present average dairy diets in Denmark
 - > Counts for a 6 % reduction of enteric methane in the farm account

AIM

To assess the impact of supplementing rape seed fat or saturated fat to diets with different grass-clover silage:maize silage ratios on

- > Enteric methane yield (methane emission per kg DMI)
- ➤ Milk production
- ➤ Milk composition
- > Rumen parameters
- > To explore potential interactions between silage type and fat source.

EXPERIMENTABETUP

Lation square

- > 4 treatments
- > 4 fistulated cows
- ➤ 4 periods of 3 weeks

Methane measured during 96 hours of each period in respiration chambers 8 rumen samples per cow covering every 3rd hour of the day

CONCLUSION

No significant interactions between fat source and silage type

> But a tendency to more negative effect on milk fat % of rape fat in maize based diets

CONCLUSION

No significant interactions between fat source and silage type

- > But a tendency to more negative effect on milk fat % of rape fat in maize based diets Effects of fat source:
- ➤ No effect for enteric methane and rumen parameters
- Significantly higher DMI, fat %, and yield of fat, protein and ECM for saturated fat

CONCLUSION

No significant interactions between fat source and silage type

- > But a tendency to more negative effect on milk fat % of rape fat in maize based diets Effects of fat source:
- ➤ No effect for enteric methane and rumen parameters
- ➤ Significantly higher DMI, fat %, and yield of fat, protein and ECM for saturated fat Effects of silage type
- > 18% lower enteric methane per kg DMI with high starch, maize based diets
- Fat %, and yield of fat and ECM were significantly lower with maize based diets
- No effect on pH and total VFA
- > Increased propionic acid and decreased acetic acid with maize based diets

PRACTICALIMPLICATIONS

An iodine product of 62-68 per kg DM is far too high to obtain normal milk production even in diets with low starch

- > Danish recommendation is a maximum iodine product of 45 per kg DM
- > Also important to validate the total nutrient composition of the diet
