SESSION 55: Host physiology/genetics and microbiome interactions – The holobiont concept EU-CIRCLES project: Evolution of pig microbiota and health under different farming conditions additives F. Correa, G. Palladino, D. Luise, D. Schicchitano, B. Giulia, S. Rampelli, P. L. Martelli, P. Trevisi

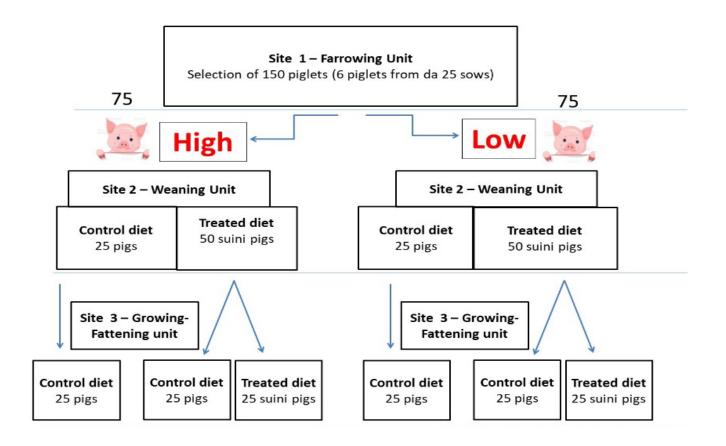

Aim of the study

The study aimed to evaluate the effect of <u>two housing systems</u> and a <u>mixture of feed</u> <u>additives</u> from weaning to growing phase on the health, performance and microbiome of pigs

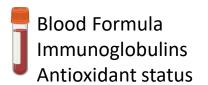

Material and methods

Sampling

| Time | Age | Site | BW | Faeces | Blood |
|-----------------|------|--------|-----|--------|-------|
| T1 ¹ | d 28 | Site 1 | 150 | 150 | |
| T2 ² | d 42 | Site 2 | 150 | 150 | 150 |
| T3 ² | d 80 | Site 2 | 150 | 150 | 150 |
| T4 ² | d 98 | Site 3 | 150 | 150 | 150 |

Material and methods

SESSION 55: **Host physiology/genetics and microbiome** interactions – The holobiont concept

EU-CIRCLES project: Evolution of pig microbiota and health under different farming conditions

F. Correa, G. Palladino, D. Luise, D. Schicchitano, B. Giulia, S. Rampelli, P. L. Martelli, P. Trevisi

- Prevotella 9
- Prevotellaceae NK3B31
- Rikenellaceae RC9
- Lactobacillus amylovorus
- Butyricicoccus porcorum

- Escherichia Shigella
- Megashaera

The dietary intervention was designed to stimulate **Smart Microbiome Modulators** (SMMs) which were defined in the
Observation phase of the project

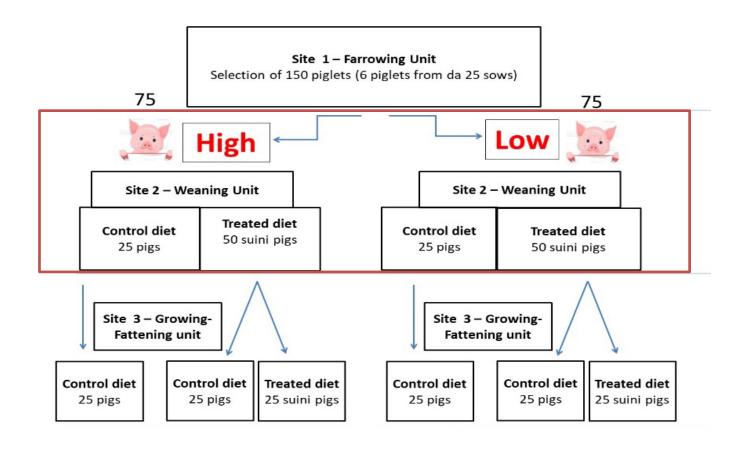

Dietary intervention

| | Weaning (T2 and T3) | Growing (T4) |
|----------------------|---------------------|--------------|
| Additive | From weaning | From 25 |
| | to 30 kg | to 50 kg |
| Benzoic acid (mg/kg) | 5000 | 5000 |
| E. faecium (mg/kg) | 35 | - |
| Muramidase (mg/kg) | 500 | - |

- Benzoic acid is able to select *Prevotella* genus (Correa et al., 2021);
- E. faecium can directly inhibit potential pathogens such as Escherichia coli (Pajarillo et al., 2015). It s also known to promoting immune system development (Bednorz et al., 2013)
- Muramidase can improve the feed efficiency and increase the peptidoglycans turnovers affecting the microbiota. It increased the *Lactobacillus* and *Butyricicoccus* genera in broilers (Wang et al., 2021; Brugaletta et al., 2022)

Results: blood formula and oxidative stress markers, T2 and T3

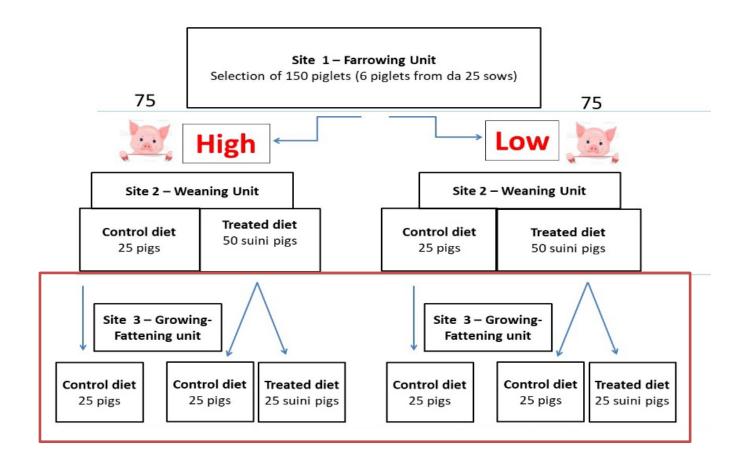

- No differences were observed at T3 for the white blood formula
- The farm confirms to play a strong stimulation of the immune system of the piglets ten days post- weaning
- Piglets can then adapt to the environmental and management stimuli
- Microbiota may contributed to stimulate the host immune response
- The oxidative status was affected by both the diet and the environment

Results: Growth performance, T2 and T3

Results: microbiota metabolism and pathway, T4

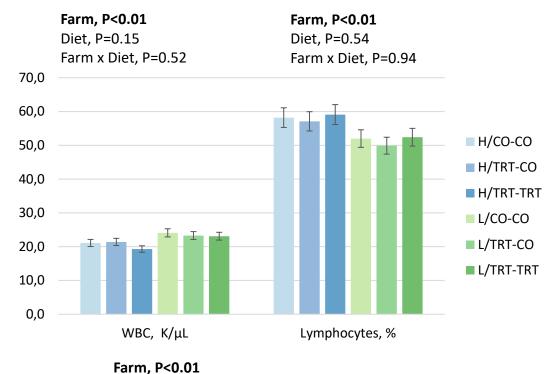

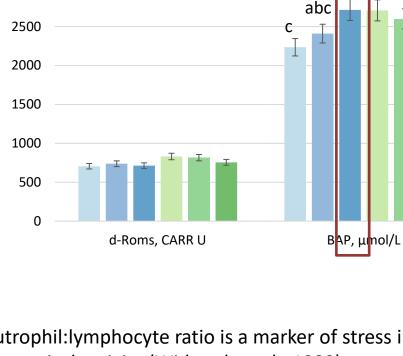

- The TRT/TRT diet reduced the microbial metabolism of AAs biosynthesis → less use of this substrates in the large intestine
- The TRT/TRT diet increased the pentose and glucuronate interconversion pathway, which is a branch pathway for complex carbohydrates catabolism → selected for bacteria capable of using complex carbohydrates.
- The reduction in peptidoglycan biosynthetic activity in the TRT/TRT diet could confirm a muramidase mechanism of action (Wang et al., 2021); the fact that it is particularly evident in the TRT/TRT group, which received only benzoic acid supplementation in the final phase, suggests a residual effect and possible synergism with benzoic acid.

Discussion and conclusion

Gut microbiota and host immune status co-evolution

Genetic Background

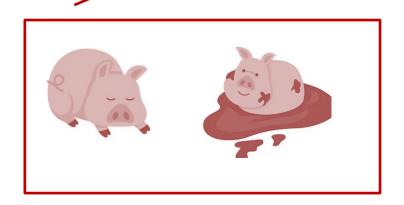

Antibiotic treatment

Environment

Age and live weight at weaning

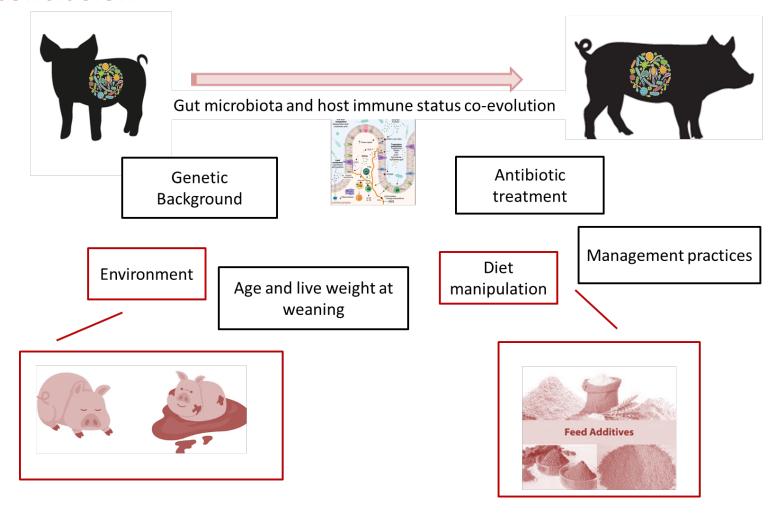

Management practices

Discussion and conclusion

The use of additives under different conditions can have different effects, highlighting the importance of evaluating feeding strategies tailored to specific farm conditions.
